Abstract

INTRODUCTION

A Quantum Drude Oscillator (QDO) is a very simple atomistic model in which the properties of an atom are encompassed in a small number of parameters. The model consists in assimilating the atom to a point particle of mass m and electric charge $-q$ attached to a fixed (infinite mass) center of charge $+q$ by a harmonic spring characterized by a frequency ω. Molecules are then defined as a collections of QDOs interactig through Coulomb interactions.

FIG. 1.   Pair of interacting QDOs.

This simple model has been extensively used in various contexts, for instance in order to tackle the electronic structure problem for isolated molecules, in particular long range interactions, as well as to study the impact of an ambient bath or of an external electric field on molecular properties [1].

Even though the harmonic oscillator nature of the atomic constituents in this model drastically simplify the complexity of problem, the all-body Coulomb interaction remains challenging. One possible way to proceed is to treat the Coulomb interaction by performing a multipolar expansion.

By truncating the multipolar expansion up to Dipole-Dipole, one obtain a quadratic Hamiltonian, hence the quantum Hamiltonian can be analytically diagonalized. Though simple, this system was shown to capture long-range phenomena in large atomistic systems [2].

In the present work, we focus instead on small (diatomic) molecules in 1d, and treat in an *analytical* way the Coulombic interactions up to Quadrupole-Quadrupole and Dipole-Octupole order, paving the way towards generalization for larger systems.

QUARTIC HAMILTONIAN FOR DIATOMIC MOLECULES

Multipolar expansion for the Coulomb potential

The Hamiltonian describing a system of N QDOs in 3d is given by:

$$H = \sum_{i=1}^{N} \left[\frac{1}{2} m_i \dot{\vec{x}}_i^2 + \frac{1}{2} m_i \omega_i^2 \vec{x}_i^2 \right] + \sum_{i<j} V_{\text{Coul}}\left(\vec{x}_i, \vec{x}_j\right) , \quad (1)$$

with the Coulomb interaction given by

$$\frac{V_{\text{Coul}}\left(\vec{x}_1, \vec{x}_2\right)}{q_1 q_2 (4\pi\epsilon_0)^{-1}} = \frac{1}{r} - \frac{1}{|\vec{r} + \vec{x}_1|} - \frac{1}{|\vec{r} - \vec{x}_2|} + \frac{1}{|\vec{r} - \vec{x}_2 + \vec{x}_1|}$$

In the multipolar expansion, this can be expressed as:

$$V_{\text{Coul}}\left(\vec{x}_1, \vec{x}_2\right) = \sum_{n \geq 0} V_n\left(\vec{x}_1, \vec{x}_2\right) , \quad (2)$$

with the following scaling behavior in terms of the distance between the centers:

$$V_n\left(\vec{x}_1, \vec{x}_2\right) \propto r^{-n+3} . \quad (3)$$

The first terms in that multipolar expansion have the following interpretation:

- $n = 0$: Dipole-Dipole interaction (DD),

- $n = 1$: Dipole-Quadrupole interaction (DQ),

- $n = 2$: Quadrupole-Quadrupole and Dipole-Octupole interaction (QQ+DO).

Using the following identity for generic vectors $\vec{r}$ and $\vec{\epsilon}$:

$$\frac{1}{|\vec{r} - \vec{\epsilon}|} = \frac{1}{r}\left[1 + \frac{\vec{\epsilon}\cdot\hat{r}}{r} - \frac{\epsilon^2 - 3(\vec{\epsilon}\cdot\hat{r})^2}{2r^2} + \frac{5(\vec{\epsilon}\cdot\hat{r})^3 - 3\epsilon^2(\vec{\epsilon}\cdot\hat{r})}{2r^3} + \frac{35(\vec{\epsilon}\cdot\hat{r})^4 - 30\epsilon^2(\vec{\epsilon}\cdot\hat{r})^2 + 3\epsilon^4}{8r^4} + \mathcal{O}\left(\frac{\epsilon^5}{r^5}\right)\right] \quad (4)$$

one can explicitly compute V_0, V_1 and V_2. Instead of writting out the expression of these potentials in full glory, let us now restrict ourselves to a system composed of $N = 2$ QDOs.

Reduced particle system

Let us move to the center of mass frame, in which the dynamics reduces to that of an effective reduced particle:

$$\vec{x} := \vec{x}_1 - \vec{x}_2 \quad (5a)$$
$$m_1\vec{x}_1 + m_2\vec{x}_2 = \vec{0}. \quad (5b)$$

In terms of the reduced variable, a straightforward computation gives us:

$$V_0(\vec{x}) = -\frac{m_1 m_2}{(m_1 + m_2)^2}\cdot\frac{x^2 - 3(\vec{x}\cdot\hat{r})^2}{4\pi\epsilon_0 r^3}, \quad (6a)$$

$$V_1(\vec{x}) = \frac{3m_1 m_2}{2(m_1 + m_2)^2}\cdot\frac{(\vec{x}\cdot\hat{r})\left(3x^2 - 5(\vec{x}\cdot\hat{r})^2\right)}{4\pi\epsilon_0 r^4}, \quad (6b)$$

$$V_2(\vec{x}) = \frac{m_1 m_2(2m_1^2 + 3m_1 m_2 + 2m_2^2)}{4(m_1 + m_2)^4} \times \quad (6c)$$
$$\times \frac{3x^4 - 30(\vec{x}\cdot\hat{r})^2 x^2 + 35(\vec{x}\cdot\hat{r})^4}{4\pi\epsilon_0 r^5}.$$

Let us now assume that the system is effectively one-dimensional, aligned along the direction on which the centers of the two QDOs are sitting. One obtain the following one-dimensional potentials for an effective particle of mass $m_1 m_2/(m_1 + m_2)$:

$$V_0(x) = \frac{2m_1 m_2}{(m_1 + m_2)^2}\cdot\frac{2x^2}{4\pi\epsilon_0 r^3}, \quad (7a)$$

$$V_1(x) = -\frac{3m_1 m_2}{(m_1 + m_2)^2}\cdot\frac{x^3}{4\pi\epsilon_0 r^4}, \quad (7b)$$

$$V_2(x) = \frac{2m_1 m_2(2m_1^2 + 3m_1 m_2 + 2m_2^2)}{(m_1 + m_2)^4}\cdot\frac{x^4}{4\pi\epsilon_0 r^5}. \quad (7c)$$

Including the contribution of the harmonic potentials present in (1) and coupling the system to an external electric field, one finally obtain the following total one-dimensional potential:

$$V(x) = \alpha x + \beta x^2 + \gamma x^3 + \delta x^4, \quad (8)$$

with the following expression of the coupling constants:

$$\alpha = -\frac{m_1 q_2 + m_2 q_1}{m_1 + m_2}\cdot\mathcal{E} \quad (9a)$$

$$\beta = \frac{m_1 m_2}{(m_1 + m_2)^2}\cdot\frac{2q_1 q_2}{4\pi\epsilon_0 r^3} + \frac{1}{2}\cdot\frac{m_1 m_2}{m_1 + m_2}\cdot\frac{m_1\omega_2^2 + m_2\omega_1^2}{m_1 + m_2} \quad (9b)$$

$$\gamma = -\frac{m_1 m_2}{(m_1 + m_2)^2}\cdot\frac{3q_1 q_2}{4\pi\epsilon_0 r^4}, \quad (9c)$$

$$\delta = \frac{2m_1 m_2(2m_1^2 + 3m_1 m_2 + 2m_2^2)}{(m_1 + m_2)^4}\cdot\frac{q_1 q_2}{4\pi\epsilon_0 r^5}. \quad (9d)$$

ANALYTIC SOLUTION OF THE SCHRÖDINGER EQUATION

In what follows, we define $k^2 := \frac{m_1 + m_2}{m_1 m_2}\frac{\hbar^2}{2}$. Let us consider the time-independent Schrödinger equation

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}x^2} + \frac{\epsilon - V(x)}{k^2}\right]\psi(x) = 0, \quad (10)$$

where the potential V is provided by (8) and (9).

Following [3], we solve the problem separately on the positive and negative real axis, and impose that the two solutions (positive and negative) $\psi_\pm$ and their first derivative match at the origin. For brievety reasons, we treat explicitly the case of the positive solution, the negative case being treated by perfoming the transformation $(x, \alpha, \beta, \gamma, \delta) \to (-x, -\alpha, \beta, -\gamma, \delta)$.

Performing the following change of variable:

$$\psi_+(x) = \exp\left[\frac{\gamma^2 - 4\beta\delta}{8k\delta^{3/2}}x - \frac{\gamma}{4k\delta^{1/2}}x^2 - \frac{\delta^{1/2}}{3k}x^3\right]\phi_+(x) \quad (11)$$

we obtain:

$$\frac{\mathrm{d}^2\phi_+}{\mathrm{d}x^2}(x) + \left[\frac{\gamma^2 - 4\beta\delta}{4k\delta^{3/2}} - \frac{\gamma}{k\delta^{1/2}}x - \frac{2\delta^{1/2}}{k}x^2\right]\frac{\mathrm{d}\phi_+}{\mathrm{d}x}(x)$$
$$+ \left[\frac{16\delta^2\left(\beta^2 + 4\delta\epsilon\right) - 8\beta\gamma^2\delta + \gamma^4 - 32\gamma\delta^{5/2}k}{64\delta^3 k^2} - \frac{8\alpha\delta^2 - 4\beta\gamma\delta + \gamma^3 + 16\delta^{5/2}k}{8\delta^2 k^2}x\right]\phi_+(x) = 0, \quad (12)$$

which is known as the so-called *tri-confluent Heun equa-* *tion.* We further perform the following change of variable,

the reason why to become clear soon:

$$\phi_+(x) = (1+x)^{\frac{4\beta\gamma\delta - \gamma^3 - 8\delta^2\left(\alpha + 2k\delta^{1/2}\right)}{16k\delta^{5/2}}} f_+(x), \qquad (13)$$

as well as map the positive real axis to the segment $[0,1]$ through the change of argument

$$z = \frac{x}{x+1}, \qquad (14)$$

and look for a solution of the obtained ODE in terms of a series expansion at zero of the form:

$$f_+(z) = \sum_{n \geq 0} c_n^+ z^n. \qquad (15)$$

Plugging the ansatz into the differential equation, we obtain the following recurrence relation between the coefficients:

$$
\begin{aligned}
&(n+1)(n+2)c_{n+2}^+ + (n+1)(A-4n)c_{n+1}^+ + [6(n-1)n + Bn + E]c_n^+ \\
&+ [C(n-1) + F - 4(n-2)(n-1)]c_{n-1}^+ + [(n-3)(n-2) + D(n-2) + G]c_{n-2}^+ = 0 \quad (n \geq 2)
\end{aligned}
\qquad (16)
$$

where the various coefficients are listed in full details in appendix. The coefficients c_0^+ and c_1^+ are to be fixed through boundary conditions, and the coeffients c_2^+ and c_3^+ are in turn fixed by the following relations

$$
\begin{aligned}
c_2^+ &= -Ec_0^+ - Ac_1^+, \\
c_3^+ &= -\frac{Fc_0^+ + (B+E)c_1^+ + 2(A-4)c_2^+}{6}.
\end{aligned}
\qquad (17)
$$

Let us similarly denote by c_n^- the coefficients in the series expansion corresponding to the solution on the negative real axis. It has been shown in [3] and [4] that the smooth matching of the two solutions at the origin can be achieved by imposing the so-called *dominant solution* to the above defined difference equations vanishes. The conditions

$$\psi_+(0) = \psi_-(0) \quad \text{and} \quad \frac{d\psi_+}{dx}(0) = \frac{d\psi_-}{dx}(0) \qquad (18)$$

lead to constraints on the initial conditions for the difference equations, namely that $c_0^+ = c_0^-$ and:

$$
\begin{aligned}
&c_1^+ - c_0^+ \left[1 + \frac{8\delta^2(\alpha+\beta) - 2\gamma\delta(\gamma+2\beta) + \gamma^3}{16\delta^{5/2}k}\right] \\
&= -c_1^- + c_0^- \left[1 - \frac{8\delta^2(\alpha-\beta) + 2\gamma\delta(\gamma-2\beta) + \gamma^3}{16\delta^{5/2}k}\right]
\end{aligned}
\qquad (19)
$$

The two sides of relation (19) are therefore equal to some quantity s, which parameterizes the solution. Now, the vanishing of the dominant solution can be achieved by imposing that the series coefficients $c_n^+(\epsilon, s)$ and $c_n^-(\epsilon, s)$ are identically 0 asymptotically in n. This provides a pair of algebraic equations in the energy variable ϵ and the *shift* variable s.

Let us make a few remarks at this stage. Imposing the vanishing of $c_n^\pm$ asymptotically in n means that practically one should fix a large value of n, denote it N, and impose that the polynomials $c_N^\pm$ vanish. One observes that c_N^- is a linear function of s. One can therefore solve explicitly for the shift variable in terms of the energy ϵ. Plugging back into the other constraint, one obtains a rational function of the form:

$$c_N^+(\epsilon, s(\epsilon)) = \frac{P_N(\epsilon)}{Q_N(\epsilon)} \qquad (20)$$

where P_n and Q_N are polynomial functions of ϵ, whose degree d_N is an non-decreasing function of N. The N zeros $\{\epsilon_i\}_{i=1}^N$ correspond then to first N energy levels of the system, provided they are not complex and that Q_N does not admit a zero of the same order.
